Factors Influencing Monetary Donations to Charitable Organizations

Corliss L. Green
Deborah J. Webb

ABSTRACT. Charitable organizations are under increasing financial pressure to attract and retain private donors. However, research examining consumer attitudes toward and motivations for giving to charity have yielded ambiguous results. A cross-disciplinary literature review suggests individual donation behavior is based on several factors including attitudes toward helping others, attitudes toward the charitable organization and various intrapersonal, social and economic motives. Using exploratory factor analysis seven factors are identified which influence monetary donations to charitable organizations. Of these seven factors, two factors measure attitudes relevant to charitable giving and five factors capture motivations for charitable giving. These measures are important to academicians, policy makers and practitioners in the development of theory and marketing strategy. *[Article copies available for a fee from The Haworth Document Delivery Service: 1-800-342-9678. States provide much of the higher education, health care, visual and performing arts and community services enjoyed by the citizenry (Feldstein and Clotfelter 1976). American charities rely on individual contributors for more than 80 percent of the funding that allows them to carry out their missions and run their organizations (Harvey 1990). Today, Americans donate in excess of \$124 billion dollars annually to nonprofit, charitable organizations (Braus 1994). For purposes of this study a charity is defined as an organization, institution, or fund established to help those who are in need.

The challenge facing charitable organizations to attract and retain donors is increasing as government support decreases, competition for individual contributions increases (Bendapudi, Singh and Bendapudi 1996), corporate donations decrease and reports of fund mismanagement abound (Epstein 1993). Thus, effective segmentation of potential donors is as important to nonprofit, charitable organizations as segmentation of potential customers is to profit seeking businesses. Effective segmentation could enable fund-raising managers to optimize their marketing strategies in the areas of promotion, positioning, pricing and distribution (Schlegelmilch, Diamantopoulos and Love 1992). Yet, the paucity of marketing research addressing helping behavior provides little guidance for nonprofit managers (Bendapudi, Singh and Bendapudi 1996). Recent efforts to gain a better understanding of helping behavior and to provide insight into the factors influencing charitable giving emphasize the significance and timeliness of this topic (e.g., Bendapudi, Singh and Bendapudi 1996; Burnett and Wood 1988; Smith and Berger 1996).

The interest in charitable giving spreads across several disciplines resulting in a broad base of literature. Both conceptual and empirical work can be found in the disciplines of psychology, sociology, social psychology, anthropology, economics and marketing. Researchers often do not incorporate the literature from other disciplines in their attempts to address questions regarding charitable behavior, which has resulted in a highly fragmented body of knowledge (Bendapudi, Singh and Bendapudi 1996; Schlegelmilch, Diamantopoulos and Love 1992). The diverse conceptual underpinnings and empirical approaches often make comparison and synthesis of findings difficult.

Researchers (e.g., Harvey 1990; Schlegelmilch 1988) have attempted to identify demographic, socioeconomic and psychographic variables that influence charitable giving and differentiate donors from nondonors. This has proven to be a difficult task due to the heterogeneity of the contributing public, charitable organizations and types of gifts. Thus, the results of this line of research have been equivocal. The purpose of this research is to

synthesize the currently fragmented literature by examining research that has been done in the context of charitable giving and to conduct an exploratory analysis of factors which influence charitable donations.

Research in consumer behavior clearly indicates that attitudes are influential in predicting behavior (Sheppard, Hartwick and Warshaw 1988). In particular, attitude toward the act (A_{act}) and attitude toward the object (A_o) measures have served as important predictors of behavior and behavioral intentions. However, none of the scales existing in the marketing literature specifically relate to donation behavior. Thus, this study provides a conceptual framework and an initial empirical effort to develop measures of attitudes toward helping less fortunate individuals and attitudes toward charitable organizations.

A multi-disciplinary review of the literature revealed several motives which influence charitable behavior. This study offers a typology for categorizing these motives. Most of the work on motives influencing charitable behavior have focused on selfless motives in which the "helper" offers aid for the benefit of the recipient. The two constructs which have been most studied are altruism and social responsibility. However, most of the research involving these constructs is not done in the context of charitable giving (i.e., making monetary donations to nonprofit organizations). The same is true for the selfish motives found in the charitable behavior literature.

Helping behavior has been defined as "behavior that enhances the welfare of a needy other, by providing aid or benefit, usually with little or no commensurate reward in return" (Bendapudi, Singh and Bendapudi 1996, p. 34). We adopt this definition for purposes of this study. The area of charitable giving encompasses several types of donations including time (e.g., Phillips 1982; Yavas, Riecken and Babakus 1993), blood (e.g., Bagozzi 1982; Burnett 1981; Knight 1983; LaTour and Manrai 1989), human organs (e.g., McIntyre et al. 1965; Pessemier, Bemmaor and Hanssens 1977) and money (e.g., Feldstein and Clotfelter 1976; Reece 1979). For this study the type of donation has been limited to monetary donations for two primary reasons: (1) one basis of the study is the impact of economic motives (i.e., financial ability and tax incentives) on charitable giving and (2) while generalizability across types of donations (i.e., time, money, etc.) is an issue, the specificity of one particular type of donation is important because factors influencing the giving of one type of donation may be quite different from those influencing other types of donations.

The ability to measure attitudes and motives toward charitable giving is important for academicians and practitioners alike. Academicians need to be able to measure these constructs in order to develop the theories needed

to understand charitable giving. Practitioners need to be able to measure these constructs to gain a better understanding of the determinants of charitable giving so they can develop more effective and efficient marketing strategies to attract and retain donors.

FACTORS INFLUENCING CHARITABLE GIVING

Attitudes

Attitudes are most often defined in the marketing literature as "global and relatively enduring evaluations of objects, issues or persons" (Petty, Unnava and Strathman 1991). In their attempts to understand donation behavior, researchers have examined attitudes toward charitable giving (e.g., Bagozzi, LaTour and Manrai 1989; Schlegelmilch 1988) and attitudes toward the charitable organization (e.g., Harvey 1990; Schlegelmilch 1988). However, multi-item scales have not been developed specifically to measure these constructs. A common weakness among previous studies is that they rely on single items to measure attitudes. Schlegelmilch (1988) found that attitudes toward giving to charity were more predictive than socioeconomic variables in discriminating between donors and non-donors. However, as is the case among previous studies, only a single item was used to measure individuals' attitudes toward the image of one particular charitable organization.

As previously discussed, research suggests that both attitudes toward charitable giving and attitudes toward charitable organizations appear to be potential determinants of contributions. This is consistent with Fishbein and Ajzen's (1975) attitude research which suggests that both A_{act} and A_o are important predictors of behavior. A_{act} and A_o measures in the marketing literature cover an array of topics including consumer products and brands, pricing practices and advertising messages. An extensive review of the academic literature, however, revealed no attitude measures specifically within the context of charitable giving. Thus, two dimensions of attitudes toward charitable giving are examined in this study:

Attitudes Toward Helping Others. This dimension is defined as global and relatively enduring evaluations with regard to helping or assisting other people.

Attitudes Toward Charitable Organizations. This dimension is defined as global and relatively enduring evaluations with regard to organizations that help individuals with the aid of private donations.

Motives

Motives are the internal factors that arouse, direct and integrate an individual's behavior (Murray 1964). As Sherry (1983) points out, the motives for giving may range from agonistic, where the donor attempts to maximize personal gain or satisfaction, to altruistic, where the donor attempts to maximize the pleasure of the recipient. It should also be recognized that more than one motive may be operant in any specific gift-giving situation.

The vast body of literature found in the disciplines of psychology, sociology, social psychology, anthropology, economics and marketing reveals a variety of motives that have been examined. Some of the donation motives that have been examined include fear, to avoid embarrassment, to acquire power, to obtain satisfaction by pleasing parent figures (Dichter 1964), recognition and belonging (American Association of Fund-Raising Council 1958), peer pressure, anticipation of personal benefits, desire to see others benefit, political gains and tax advantages (Margolis 1982; Rubin and Thorelli 1984). However, due to the highly fragmented nature of the knowledge base, most studies only examine the motives common to a specific discipline. Thus, a piecemeal understanding based on studies examining the relationship between charitable behavior and individual motives specific to a particular discipline has emerged. Furthermore, by measuring individual motives for charitable behavior researchers fail to recognize the commonality among some of these constructs, which must be unraveled to attain a better understanding of charitable behavior.

The majority of motives prevalent in the extant literature fall within one of three categories: intrapersonal, social or economic. Intrapersonal motives include altruism and negative state relief. Social motives include social responsibility, social exchange and social conformity. Economic motives include financial ability and tax incentives. Each of the motives within these categories can further be classified as either selfish, where individuals are driven to give based on what they will receive in return, or selfless, where individuals are motivated to give out of the kindness of their hearts. The following sections discuss each of the motives found in the literature. Then, a cross-disciplinary typology of motives is offered.

Intrapersonal Motives

Intrapersonal motives are those derived from an individual's internal state. There has been an ongoing philosophical debate spanning two centuries regarding the existence of altruism (Batson 1987). The central question is whether humans are capable of purely unselfish acts or whether all

helping behavior arises out of egoistic and self-serving motives (Batson 1987; Simmons 1991). On the one hand, Batson and his colleagues contend that altruism in its truest sense does exist. On the other, Cialdini and his cohorts purport that almost all helping behavior is based on selfish motives.

Altruism. Altruism is helping behavior that is intentional and voluntary, which seeks to increase another's welfare, instead of one's own and for which no external reward is expected (Batson 1987; Piliavin and Charng 1990; Simmons 1991). In essence, altruism is a selfless form of motivation. Altruism has been studied extensively in the disciplines of social psychology, sociology and psychology and to some extent in economics, political behavior and sociobiology (see Piliavin and Charng 1990 for review). As Piliavin and Charng (1990) point out, altruistic behavior can take many different forms. This is reflected in the variety of scales researchers have used to measure altruism (e.g., Rushton, Chrisjohn and Fekken 1981; Simmons 1977).

The most frequently named psychological mechanism of altruistic motivation is empathy (Batson 1987; Hoffman 1981; Simmons 1991). Batson et al. (1988, p. 52) define empathy as "an other-oriented emotional response congruent with the perceived welfare of another person [which] can evoke motivation to help that person." It is proposed to result from the perceiver adopting the perspective of the other person (Batson 1987). A great deal of empirical research has been conducted that lends support to the empathy-altruism hypothesis (see Batson 1987 for review).

Negative State Relief. Cialdini and his colleagues (e.g., Cialdini, Kenrick and Baumann 1982; Cialdini et al. 1987) believe that helping behavior is based on the egoistic motive of personal mood management as opposed to selfless motivation. According to the negative state relief hypothesis (Cialdini, Kenrick and Baumann 1982), helping behavior may result from a person's need or desire to relieve personal distress elicited by the suffering of another. Some scholars posit that the personal distress is caused by anxiety, while others claim it is caused by sadness (Simmons 1991).

While the debate continues in the social psychology literature, some researchers have chosen to minimize the differences between altruistic and egoistic motivations (Hoffman 1981) or to examine these motives in combination (Stiff et al. 1988) in an empathy-distress-altruism model (Simmons 1991; Stiff et al. 1988). Others have found it very difficult to differentiate between altruistic and egoistic motives when research is conducted in the real world as opposed to laboratory settings (Simmons 1991). The emerging consensus appears to be that both altruistic and egoistic helping motives exist (Piliavin and Charng 1990; Simmons 1991).

Social Motives

Social motives are those stemming from social norms, which can be derived from a number of social institutions including family, school, church or culture. According to the sociological literature, charitable behavior is often driven by norms. As previously discussed, altruism and negative state relief are posited to be the psychological mechanisms at the individual level that result in helping behavior. Likewise, norms are viewed as the sociological mechanism at the societal level that result in helping behavior (Simmons 1991). Berkowitz (1972) maintains that the norm of social responsibility is the underlying motive behind helping behavior. Other scholars (e.g., Homans 1961; Mathur, Smith and Moschis 1992) contend that the norms outlined in social exchange theory are the operant determinants of helping behavior. The primary difference between these norms is, once again, whether the benefactor is acting in a selfless or selfish manner.

Social Responsibility. Berkowitz (1972) posits that there is probably much more selfless action to help others without any expectation of reciprocation or reward than exchange theory would suggest. He contends that such behavior occurs due to the operation of social rules based on internalized standards of conduct. Thus, a socially responsible person will tend to help people even when there is nothing to be gained from it. The norm of social responsibility is the social rule most often associated with charitable behavior. Smith (1980, p. 755) defines the norm of social responsibility as the "social norm that dictates that an individual acting alone must 'get involved' or 'feel responsible' for the safety and well being of another." For purposes of this research social responsibility motivations are defined as internalized standards of conduct without any expectation of reciprocation or reward in return.

Social Exchange. Homans (1961, p. 13) captures the essence of social exchange theory in his description of social behavior as an "exchange of activity, tangible or intangible, and more or less rewarding or costly, between at least two persons." According to this perspective, people engage in activities when they perceive the benefits to equal or exceed the costs of participating in the activities. The incomes and/or the outcomes of these activities can be either material or psychosocial (Mathur, Smith and Moschis 1992). Thus, for this study social exchange motivations are defined as the material or psychosocial rewards helping behavior is expected to bring the donor.

In the marketing literature an exchange dimension has been identified in both interpersonal giving (Sherry 1983) and self-giving (Mick and DeMoss 1990). Furthermore, Mathur, Smith and Moschis (1992) found

partial support for an exchange theory explanation of elderly people's motivations for charitable giving.

Social Conformity. Social conformity has been associated with a variety of consumption behaviors ranging from product choice (Bearden and Rose 1990) to illicit drug and alcohol consumption (Rose, Bearden and Teel 1992). The underlying premise of research on social conformity is that individuals are influenced by their sensitivity to social cues. Thus, in this study social conformity motivations are defined as sensitivities to social cues or norms concerning giving behavior.

While researchers have examined the influence of social norms on some forms of charitable giving, such as blood donations (e.g., LaTour and Manrai 1989) little work has been done in this area with regard to monetary donations. As with any type of consumption behavior it might be expected that monetary donations to nonprofit organizations may be moderated by a sensitivity to social cues or norms concerning giving behavior. On the other hand, it has long been recognized that interpersonal influence is affected by the conspicuousness of the consumption (e.g., Bearden and Etzel 1982). Given the private nature of many monetary donations, social conformity may not play as significant a role as it does in other types of charitable behavior.

Economic Motives

In economic terms, charitable giving is "the voluntary one-way transfer of economic goods to individuals or organizations outside the family unit" (Reece 1979, p. 142). Economists struggle with the paradox of altruism. Economic man is bolstered by the fallacy of composition: what is best for each individual is not necessarily best or even good for all (Samuelson 1993). However, as Reece (1979) explains, charitable behavior has been rationalized in the economic literature in basically two different ways.

Financial Ability. One economic rationalization for charitable behavior is based on the hypothesis that there is an 'alliance' among the members of the society. In this perspective, individuals make contributions to maintain the organization of society because it is a collective good (De Alessi 1975). Economists also consistently find that charitable giving increases as income level increases (e.g., Feldstein and Clotfelter 1976; Reece 1979) offering support for this perspective.

Tax Incentives. Becker (1974) is credited with formulating a model based on the hypothesis that individuals' preferences are defined by their own and other peoples' levels of consumption. According to this model, a donor's level of giving is directly related to his or her income, and is inversely related to the price of the contribution. In addition, the donor's

level of giving is inversely related to the recipient's level of consumption without the benefit of the donor's contribution. In support of this view, economists consistently find that the tax deductibility of charitable contributions is an important determinant of one's level of giving (e.g., Feldstein and Clotfelter 1976; Reece 1979).

As a first step in the process of integrating the literature and measuring motives related to charitable behavior, a cross-disciplinary typology of motives was developed (see Table 1).

METHODOLOGY

Item Generation

A review of the extant literature resulted in a formulation of the conceptual underpinnings involved in charitable giving as well as an extensive list of items used to measure the numerous factors posited to influence this behavior. Following the process outlined by Churchill (1979), specific construct definitions for each of the attitudes and motives presented above were developed based on this review. Using these definitions as a starting point, a pool of 78 items was generated to tap the domains of: (1) attitudes toward and (2) motives for making monetary contributions to charitable organizations. This initial pool of items consisted of items used in other scales, items created by the authors from the conceptual ideas presented in theoretical articles and extensively revised items. Most of the items that required major revisions had either been used to measure other forms of giving or had not been Likert-type items in previous research.

Content Validity

First, three expert judges (two marketing professors and a doctoral student in marketing) were asked to code each of the 78 items. Judges

TABLE 1. Typology of Motives for Charitable Behavior

	Intrapersonal	Social	Economic
Selfless	Altruism	Social Responsibility	Financial Ability
Selfish	Negative State Relief	Social Exchange Social Conformity	Tax Incentives

were given a coding scheme which provides specific construct definitions for each of the attitudes and motives (see Appendix A) and were asked to use this as the basis for coding the 78 items. A priori, it was decided that only those items coded identically by at least two of the three judges would be retained. Based on the evaluations of the first group of expert judges 14 items were eliminated from the initial pool resulting in the retention of 64 items.

Similar to procedures followed by other marketing researchers (e.g., Lichtenstein, Netemeyer and Burton 1990) content validity was further assessed by a second set of three judges. The 64 retained items were grouped by construct according to the evaluations of the first set of judges. Then, the second group of judges¹ (two marketing professors and a doctoral student in marketing) were asked to rate each item as clearly representative, somewhat representative, or not representative of the construct to which it had been assigned. Only items rated either clearly representative or somewhat representative by at least two of the three judges were retained. This process resulted in the elimination of 17 additional items, leaving 47 items.

The remaining 47 items were randomly ordered and incorporated into a questionnaire that was administered to 307 graduate and undergraduate evening students at a metropolitan university in the southeast. This sample was considered appropriate since the student body is quite diverse and is different from traditional students at most universities. The majority of the sample are employed full-time and function in the same manner as other citizens in the metropolitan area. Individuals within the sample were also significantly older than traditional university students. This was confirmed by the fact that the respondents ranged in age from 19 to 46 years of age with a mean age of 27.8 years. Furthermore, 80.1 percent of the respondents reported that they had donated to a charitable organization within the past year.

Analyses

Based on the categorization of items by the judges, items with corrected item-to-total correlations less than 0.40 were dropped from the analysis to increase the internal consistency of the scales (Saxe and Weitz 1982). As a result of this process, 10 items were eliminated. Once this step in the analysis was performed, all of the social responsibility items had been eliminated and only two social conformity items remained.

Since attitudes and motives are clearly two different constructs, two factor analyses ($n = 307$) were run using the remaining 35 items. The first factor analysis included 12 items judged representative of attitudes toward

charitable giving. The second factor analysis consisted of 23 items judged representative of the various motives for charitable giving. VARIMAX rotation was used to facilitate interpretation of the factors.

As expected, in the first analysis two distinct factors emerged as representative of attitudes relevant to charitable giving with eigenvalues of 5.52 and 1.46 which explained 58.2% of the variance. One factor is comprised of 5 items measuring attitudes toward helping others and the other factor is comprised of 7 items measuring attitudes toward charitable organizations. The factor analysis proved consistent with the opinions of the judges.

In the second factor analysis, five rather than the anticipated six factors emerged. The two items remaining in the analysis which had been judged to be representative of social conformity were split between two different factors. One item loaded negatively (factor loading = -0.3539) with the items judged representative of altruism, while the other loaded (factor loading = 0.4935) with the items judged representative of social exchange. Given that the only two items remaining of the seven items judged representative of social conformity did not emerge as a factor, it was dropped from the analysis leaving a total of 21 items judged representative of the five remaining motives of charitable giving.

Once these two items were dropped, five distinct factors emerged as representative of motives relevant to charitable giving as anticipated. These five factors had eigenvalues of 4.10; 3.47; 2.59; 1.52 and 1.31 and accounted for 61.9% of the variance. These five factors measure the following motives: altruism (5 items); negative state relief (5 items); social exchange (4 items); financial ability (3 items) and tax incentives (4 items). In addition, the individual items loaded on the factors consistent with the judges' evaluations.

The emergence of distinct factors, each comprised of the appropriate items provides evidence for discriminant validity for the dimensions explicated for each of these constructs. In addition, the variance of each construct explained exceeds the advocated rule of thumb of $\geq .50$ (Fornell and Larcker 1981).

Reliability analysis using Cronbach's (1951) alpha was conducted to determine the internal consistency for each of the scales. One item was eliminated to increase the reliability of the scales. Thus, the resulting seven scales are comprised of a total of 32 items (see Table 2). Furthermore, the reliability of the scales meets or exceeds an acceptable standard of .70 (Nunnally 1979) with the exception of altruism, which comes very close to meeting this standard with an alpha of 0.69.

Results

Attitudes relevant to charitable giving are measured using two scales:

Attitudes Toward Helping Others (5 items; $\alpha = 0.83$). Thirteen items were identified as reflecting attitudes toward helping others by the first set of judges. However, only 7 of these were judged as representative of the construct by the second set of judges. Two of the 7 items were eliminated due to corrected item-to-total correlations less than 0.4, leaving 5 items in the scale.

Attitudes Toward Charitable Organizations (7 items; $\alpha = 0.85$). The first set of judges identified 12 items which reflected attitudes toward charitable organizations. But, once again only 7 of these were judged as representative of the construct by the second set of judges. All 7 of these items were retained in subsequent analysis.

Originally, seven different motives for charitable giving were postulated. However, two of these did not hold together in the analysis (i.e., social responsibility and social conformity). Thus, motives for charitable giving are represented by five scales. The results were as follows:

Altruism (5 items; $\alpha = 0.69$). The first set of judges identified 8 items as reflecting altruism. Yet, once again, only 7 of these items were judged as representative of altruism by the second set of judges. Two of the 7 items were eliminated due to corrected item-to-total correlations less than 0.4, leaving 5 items in the scale. These 5 items were retained in subsequent analysis.

Negative State Relief (5 items; $\alpha = 0.78$). The Negative State Relief scale measures helping behavior motivated by a person's need or desire to relieve personal distress elicited by the suffering of another. The personal distress may be caused by anxiety or sadness. Six items were identified as reflecting the negative state relief construct by the first set of judges. The second set of judges agreed that 5 of these items were representative of the construct. The same 5 items were retained in subsequent analysis.

Social Exchange (4 items; $\alpha = 0.70$). The Social Exchange scale measures helping behavior motivated by the material or psychosocial rewards these actions are expected to bring the donor. The first set of judges identified 5 items as reflecting the social exchange construct. However, only 4 of these were judged as representative of the construct by the second set of judges. All of these items were retained in the final scale.

Tax Incentives (3 items; $\alpha = 0.90$). The Tax Incentives scale measures an individual's motivation based on the personal financial gain realized from the deductibility of charitable donations. Four items were judged to

reflect this construct by both sets of judges. One item was deleted to increase the reliability of the scale resulting in a final scale of 3 items.

Financial Ability (3 items; $\alpha = 0.88$). The Financial Ability scale taps motivation based on the individual's financial ability to donate to a charitable organization. Both sets of judges agreed on 4 items reflecting financial ability. One of these items was dropped because its corrected item-to-total correlation was less than 0.4. The remaining 3 items were retained to comprise this scale.

DISCUSSION

This study provides a catalyst for other work in this area. It integrates the cross-disciplinary literature and offers a framework for future research. The typology developed in this study may serve as a guide for scholars conducting empirical research in this area. The primary focus of the marketing literature examining consumer attitudes and motivations has been measuring and predicting factors influencing "profit-oriented" behaviors (i.e., those behaviors leading ultimately to the profit line of businesses and corporations). It is clear, however, that attitudes toward and motives for patronizing nonprofit, charitable organizations are often quite different.

The measures developed in this study are an important step for research aimed at understanding charitable behavior. They provide a contribution to the future development of comprehensive models which incorporate attitudes and motives as predictors of charitable behavior. The precedent to modeling, however, is measurement and the existing literature lacks valid, reliable measures of constructs relating to charitable giving, particularly those associated with the selfish or egoistic nature of donating to charity.

An important area for future research is the development of more concrete and discriminating construct definitions of the selfless motives examined in this study, particularly for altruism and social responsibility. Both are derived from the cultural value of humanitarianism and can be viewed as complementary concepts. Although the social responsibility scales found in the literature were not within the charitable giving context, several of the items making up the scales were found to be very similar to altruism (e.g., Berkowitz and Lutterman 1968; Rushton et al. 1981). The definition of social responsibility refers to "an internalized standard of conduct," which makes it difficult to differentiate between psychological (intrapersonal motives) and sociological (social motives) constructs. Thus, in assessing content validity there may not have been enough differenti-

ation between social responsibility and altruism for both to have been clearly identified as two separate constructs.

Within the marketing literature, the social conformity construct has been primarily associated with conspicuous consumption (e.g., product and brand choice). Thus, the likelihood of conforming to a behavior is stronger when the behavior is socially visible (Bearden and Etzel 1982) than when it is performed privately by the individual. Therefore, it is not surprising that this construct was not represented in the motives for charitable giving. Giving to charity is often a personal act done privately rather than conspicuously in the presence of others, with the exception of small dollar amounts sought in public domains (e.g., store fronts, malls, church collection plates). Specifically, for larger dollar amounts (e.g., \$20 or more) most donations tend to be done in private.

Of course, the validity and reliability of the scales developed in this study need to be further examined in future research. While we have every reason to believe that the nontraditional student sample used in the development of the measures is appropriate, varied sampling frames are needed to confirm this assumption. Also, future efforts to examine the validity and reliability of the measures developed could employ confirmatory factor analyses utilizing structural equation modeling (SEM).

In addition to extending the research in an effort to confirm the developed measures and examine the link between attitudes, motives and charitable behavior, the scales may be used to make predictions between attitudes, motives and other related constructs. For example, it has been suggested that one's self-concept is related to his or her behavior as a consumer. Thus, it would be interesting to examine the relationship between self-concept and the motivation to give to charity. In addition, personal and cultural values have been commonly used to differentiate the behaviors of individuals. Another area of research using the developed scales could be the assessment of the impact of values in predicting motivations associated with charitable giving. This would be particularly important in the context of examining charitable behavior cross-culturally.

The measures developed in this study also provide implications for managers of nonprofit, charitable organizations. Because private donations are essential to the day-to-day operations of charities in this country, effective segmentation of potential donors is critical. However, demographic variables, which have been heavily relied upon by many organizations, provide little meaningful information for purposes of segmentation. For example, simply knowing that a potential donor makes a certain amount of money or lives in a particular type of neighborhood is no indication of how or why they donate. There may be certain segments of

consumers with different motivations than others (i.e., tax incentives vs. altruistic motives), regardless of demographic background. Thus, managers may use the motives examined in this study to discriminate between donor types and apply the typology developed to gather pertinent information about past donors.

AUTHOR NOTE

Corliss L. Green received her PhD in marketing from Florida State University. Her research has appeared in the *Journal of Advertising Research* and the *Journal of Retailing*. Her primary research interests are in the areas of sales promotion, social marketing, and consumer research emphasizing the buying behavior of ethnic consumers.

Deborah J. Webb's primary research interest is in the area of consumer behavior.

NOTE

1. The second set of judges consisted of different examiners than the first set of judges; a total of six judges were used in the analysis.

APPENDIX A. Construct Definitions

Attitudes—"global and relatively enduring evaluations of objects, issues or persons" (Petty, Unnava, and Strathman 1991).

A1. Attitudes Toward Helping Others—Item reflects global and relatively enduring evaluations with regard to helping or assisting other people.

A2. Attitudes Toward Charitable Organizations—Item reflects global and relatively enduring evaluations with regard to the non-profit organizations that help individuals.

A9. Attitude—None of the Above—Item reflects global and relatively enduring evaluations other than those regarding helping others or charitable organizations.

Motivations—The internal factors that arouse, direct and integrate an individual's behavior (Murray 1964).

Intrapersonal Motives—Motives derived from within the individual.

I1. Altruistic—Item reflects helping behavior that is intentional and voluntary, which seeks to increase another's welfare, instead of one's own and for which no external reward is expected (Batson 1987). (Selfless)

I2. Negative State Relief—Item reflects helping behavior motivated by a person's need or desire to relieve personal distress elicited by the suffering of another. The personal distress may be caused by anxiety or sadness. (Selfish)

I9. Intrapersonal Factor—None of the Above

Social Motives—Motives derived from social norms, which can be derived from a number of social institutions including family, school, church or culture.

S1. Social Responsibility—Item reflects helping behavior motivated by an internalized standard of conduct without any expectation of reciprocation or reward in return. (Selfless)

APPENDIX A (continued)

Social Motives

- S2. Social Exchange**—Item reflects helping behavior motivated by the material or psychosocial rewards these actions are expected to bring the donor. (Selfish)
- S3. Social Conformity**—Item reflects helping behavior motivated by a sensitivity to social cues or norms concerning their giving behavior.
- S9. Social Factor—None of the Above**

Economic Motives—Motives involving financial implications.

- E1. Tax Benefits**—Item reflects motivation based on the personal financial gain realized from the deductibility of charitable donations.
- E2. Financial Ability**—Item reflects motivation based on the individual's financial ability to donate to a charitable organization.
- E9. Economic Factor—None of the Above**
- 99. Neither an Attitude or Motivation**—Item does not belong in any of the above categories.
